

Problem Statement : Improving Test Coverage and Risk Management for an Insurance Claims Processing Platform

Background:

Your organization operates a claims processing platform for multiple insurance products (auto, health, property). The platform is used by agents, customers, and third-party assessors.

The platform is built on a mix of legacy and modern microservices.

There are 8 scrum teams: 3 for product-specific modules, 3 for platform services, and 2 for third-party integrations.

Each team has 2 developers and 1 QA engineer.

Releases are bi-weekly, but major releases are quarterly.

50% of production incidents are related to claims calculation errors and integration failures.

Test automation exists for platform services, but not for product modules or third-party integrations.

Manual regression testing is performed, but coverage is unknown and not tracked.

No risk-based testing approach is in place; all features are tested equally.

No centralized test strategy or metrics for claims accuracy, integration reliability, or customer experience.

Task:

Develop a risk-based test strategy and coverage plan to improve claims accuracy, integration reliability, and overall quality for the insurance platform, including recommendations for automation and metrics.
